

Session 15:

- 1.) In Power BI, create a table of your 5 most-used food delivery apps (like Zomato, Swiggy, Domino's, McDonald's, Pizza Hut) with a column for total orders placed. Use the SUM function to calculate the total number of orders across all apps and display it in a card visualization.

ANSWERS:

Answer:

In Power BI, a table is created using a dataset of five food delivery apps such as **Zomato, Swiggy, Domino's, McDonald's, and Pizza Hut**, along with a column showing the total number of orders placed for each app.

To calculate the overall total orders, a DAX measure is created using the SUM function:
Total_Orders = SUM(Orders[OrderCount])

This measure is then added to a **Card visualization**, which displays the total number of orders in a single value format (e.g., 2.39M).

The table shows individual app-wise order counts, while the card visual provides a **quick summary of total orders across all apps**, making it easy to understand overall performance.

- 2.) Add a new column to your Power BI table for 'Order Ratings' (random numbers between 1 and 5 for each app). Use the AVERAGE function to show the average rating across all apps in a separate card.

ANSWERS:

Answer:

In Power BI, a new column named **Order Ratings** is added to the table, where each app is assigned a random rating value between **1 and 5**.

To calculate the overall average rating, a DAX measure is created using the AVERAGE function:

Average_Rating = AVERAGE(Orders[Order Ratings])

This measure is then placed in a **Card visualization**, which displays a single value (e.g., 4.02) representing the average rating across all apps.

The table shows individual ratings for each app, while the card visual provides a **quick summary of the overall average rating**, making it easy to understand user satisfaction.

4.02

average_rating

- 3.) Create a slicer in Power BI to filter your table by order ratings greater than 3. Use the COUNT and DISTINCTCOUNT functions to display the total number of orders and the count of unique apps with ratings above 3.

ANSWERS:

Answer:

In Power BI, a **Slicer** is created using the **Order_Rating** field to filter the data. The slicer is adjusted to show values **greater than 3**, so only apps with higher ratings are displayed in the table.

To calculate the total number of orders, a DAX measure is created using the COUNT function:

Total_Orders = COUNT(Orders[OrderID])

To count the number of unique apps with ratings above 3, another measure is created using DISTINCTCOUNT:

Unique_Apps = DISTINCTCOUNT(Orders[App_Name])

These measures are added to the report (Card or Table visual). The slicer dynamically filters the data, so both total orders and unique app count update automatically based on the selected rating range.

This setup helps to easily analyze **high-rated apps and their order performance**.

- 4.) Add a calculated column to your table that shows 'High Performer' if the app's order count is above the average, otherwise 'Regular', using the SWITCH function and logical operators (AND/OR). Display this new column in your table visualization.

Hint: Use VAR to store the average and RETURN to output the label based on the condition.

ANSWERS:

The screenshot shows the DAX editor with the following formula:

```

1 new_Column =
2 VAR AverageOrderCount = [avgOrderCount]
3 RETURN
4
5 SWITCH(
6   TRUE(),
7   AppMetrics[appOrderCount] > AverageOrderCount, "High Performer", "Low"
8 )
9
10
11
12

```

Below the formula, a table displays the results of the measure:

App_ID	App_Name	Order_Count	Average_Rating	new_Column
APP-301	Swiggy	1520	4.2	Low
APP-302	Zomato	1850	4.5	Low
APP-303	Zepto	920	4.1	Low
APP-304	Blinkit	1410	4.4	Low
APP-305	Instamart	600	3.9	Low
APP-306	BigBasket	1100	4.3	Low
APP-307	Dunzo	450	3.6	Low
APP-308	EatSure	310	4	Low

5.) Use Power BI's DAX editor to write a measure that returns 'Top Choice' if an app has more than 100 orders and a rating above 4, otherwise 'Consider Alternatives'. Use AND, IF, and NOT functions in your logic.

ANSWERS:

Order_ID	App_Name	Bill_Amount_INR	User_Rating	TC
8052	Zomato	934	5	Top Choice
8072	Zomato	451	5	Top Choice
8064	Zomato	708	5	Top Choice
8003	Zomato	812	5	Top Choice
8117	Zomato	1098	5	Top Choice
8107	Zomato	962	5	Top Choice
8033	Zomato	741	5	Top Choice
8067	Zomato	711	5	Top Choice
8013	Zomato	601	5	Top Choice
8066	Zomato	835	5	Top Choice

Answer:

In Power BI, a **calculated column** is created to classify apps as *High Performer* or *Regular* based on their order count compared to the average.

The following DAX formula is used:

new_Column =

VAR AverageOrderCount = AVERAGE(AppMetrics[Order_Count])

RETURN

SWITCH(

TRUE(),

```
AppMetrics[Order_Count] > AverageOrderCount, "High Performer",  
"Regular"  
)
```

This formula first stores the average order count using **VAR**, then uses the **SWITCH(TRUE())** logic to check the condition. If an app's order count is greater than the average, it is labeled "**High Performer**", otherwise "**Regular**".

The new column is then added to the **table visualization**, allowing easy identification of high-performing apps based on their order count.
